

BEFORE THE  
STATE OF NEW YORK  
PUBLIC SERVICE COMMISSION

---

In the Matter of

National Grid PLC and KeySpan Corporation - Proposed Merger

Case 06-M-0878

The Brooklyn Union Gas Company d/b/a KeySpan Energy Delivery  
New York - Gas Rates

Case 06-G-1185

KeySpan Gas East Corporation d/b/a KeySpan Energy Delivery  
Long Island - Gas Rates

Case 06-G-1186

January 2007

---

Prepared Testimony of:

CONSTRAINTS PANEL

Thomas Paynter  
Supervisor of Regulatory  
Economics  
Office of Regulatory Economics

Edward C. Schrom, Jr.  
Power Systems Operations  
Specialist  
Office of Electricity and  
Environment

State of New York  
Department of Public Service  
Three Empire State Plaza  
Albany, New York 12223-1350

1 Q. Please state your full name and business  
2 address.

3 A. My name is Thomas S. Paynter. My business  
4 address is Three Empire State Plaza, Albany, New  
5 York 12223-1350.

6 Q. By whom are you employed and in what capacity?

7 A. I am employed by the New York State Department  
8 of Public Service as Supervisor of Regulatory  
9 Economics in the Office of Regulatory Economics.

10 Q. Please describe your educational background.

11 A. I received a Ph.D. in Economics from the  
12 University of California at Berkeley (1985),  
13 with fields in econometrics and labor economics.  
14 I have a B.A. in Physical Science and a B.A. in  
15 Economics, also from the University of  
16 California at Berkeley (1975). I am a member of  
17 the American Economic Association.

18 Q. Please describe your professional experience.

19 A. From 1983 to 1986, I was an Assistant Professor  
20 of Economics at Northern Illinois University,  
21 where I taught graduate and undergraduate  
22 courses in economic theory. From 1986 to 1990,

1 I was employed by the Illinois Commerce  
2 Commission as a Senior Economic Analyst in the  
3 Policy Analysis and Research Division; I was  
4 also a member of the Electricity Subcommittee of  
5 the National Association of Regulatory Utility  
6 Commissioners, and authored an article  
7 concerning coordination and efficient pricing  
8 for independent power producers, "Coordinating  
9 the Competitors," published by The Electricity  
10 Journal in November 1990. I joined the New York  
11 Department of Public Service in November of  
12 1990.

13 Q. Have you testified previously before the New  
14 York Public Service Commission?

15 A. Yes, I have testified in numerous rate cases and  
16 other proceedings before the Commission. I have  
17 also testified before the Federal Energy  
18 Regulatory Commission (FERC) and the New York  
19 State Board on Electricity Generation Siting and  
20 the Environment.

21 Q. What are your current responsibilities?

- 1 A. My current responsibilities include analyzing  
2 competitive issues, efficient pricing, marginal  
3 costs, and regulatory policies. I have been a  
4 member of a staff team responsible for analyzing  
5 and commenting upon the system planning and  
6 pricing rules of the New York Independent System  
7 Operator (NYISO), since its inception. I have  
8 participated in numerous all-parties meetings  
9 related to the implementation of the NYISO  
10 tariff, including market power mitigation. I am  
11 a regular participant at the NYISO's Scheduling  
12 and Pricing, Market Structures, Installed  
13 Capacity, and Electric System Planning Working  
14 Groups; these all-party working groups develop  
15 proposals for NYISO rules and procedures, which  
16 are then subject to votes by market participants  
17 at the Business Issues, Operating, and  
18 Management Committees, before being acted upon  
19 by the NYISO Board.
- 20 Q. Please state your full name and business  
21 address.

1 A. My name is Edward C. Schrom, Jr. and my business  
2 address is Three Empire State Plaza, Albany, New  
3 York.

4 Q. By whom are you employed and in what capacity?

5 A. I am employed by the New York State Department  
6 of Public Service as Power System Operations  
7 Specialist in the Bulk Transmission Systems  
8 Section, Office of Electricity and Environment.

9 Q. Please summarize your educational background and  
10 professional experience.

11 A. I graduated from Rochester Institute of  
12 Technology with a Bachelor of Science in  
13 Electrical Engineering Degree in June 1974. I  
14 have taken graduate courses in Electric Power  
15 Engineering at Rensselaer Polytechnic Institute  
16 and have attended several seminars given by  
17 general Electric's Electric Utility System  
18 Engineering Design Group and its Power System  
19 Management Department. In 1977, I began working  
20 for the Department of Public Service as a Power  
21 Transmission Planner in the Power Division,  
22 System Planning Section. In late 1980, I was

1 appointed to the position of Senior System  
2 Planner. In the fall of 1990, I was appointed  
3 to the position as a Power Generation Planner  
4 and in August of 1998, I was appointed to the  
5 position of Power System Operations Specialist.  
6 I have testified previously in Article VII  
7 transmission siting cases, Article VIII and  
8 Article X power plant siting cases, the State  
9 Energy Master Plan (SEMP) III proceeding, in  
10 numerous rate cases, and on the qualifying  
11 status of an IPP plant before FERC.

12 Q. Do you belong to any professional associations?

13 A. Yes, I am a member of the Institute of  
14 Electrical and Electronics Engineers (IEEE) and  
15 the IEEE Power Engineering Society.

16 Q. Are you a licensed professional engineer?

17 A. Yes, I am registered as a professional engineer  
18 in the State of New York.

19 Q. What is the purpose of the Panel's testimony?

20 A. The Panel's testimony supplements that of the  
21 Merger Panel, which, among other things  
22 addresses the potential for the merger to

1           violate the Commission's policy on vertical  
2           market power, as provided by its Vertical Market  
3           Power Policy Statement (CASE 96-E-0090, et al.,  
4           Statement of Policy Regarding Vertical Market  
5           Power, July 17, 1998). (VMP Statement) Our  
6           testimony responds to the claims by National  
7           Grid witnesses Schiavone and Saidi that the  
8           merged company would have no ability to increase  
9           downstate prices by increasing transmission  
10          constraints and that, even if it had such  
11          ability, any attempt to exercise it would be  
12          mitigated by the rules and procedures of the  
13          NYISO. For example, we analyze National Grid's  
14          ability to schedule or extend outages in order  
15          to increase downstate prices and thus benefit  
16          the merged company's downstate generation.

17    Q.    Can you briefly summarize your conclusions?

18    A.    First, the merged company would have the ability  
19          to increase downstate prices by increasing  
20          transmission constraints. Second, the rules and  
21          procedures of the NYISO do not in fact mitigate  
22          such market power. Finally, the merger would

1           compromise the governance of the NYISO and make  
2           it difficult to strengthen the NYISO rules and  
3           procedures to mitigate such market power.

4

5   Overview of Vertical Market Power Concerns

6   Q.    Please briefly describe KeySpan's generation  
7           assets.

8   A.    KeySpan Ravenswood owns about 2,400 Megawatts  
9           (MW) of generating capacity in New York City  
10           (NYC), which generated almost 6.4 million  
11           Megawatt-hours (MWh) of energy in 2005. (NYISO:  
12           2006 Load and Capacity Report, Table III-2)  
13           This indicates an average capacity factor of  
14           about 30% in 2005, i.e. Ravenswood capacity  
15           generated on average about 30% of the its  
16           maximum output (6.4 million MWh divided by 2,400  
17           MW divided by 8760 hours per year). KeySpan  
18           Ravenswood sells capacity and energy at market  
19           prices in New York City. KeySpan also owns  
20           about 4,200 MW of generating capacity on Long  
21           Island (LI), which generated almost 11.4 million  
22           (MWh) in 2005 (NYISO: 2006 Load and Capacity

1        Report, Table III-2). The LI capacity and  
2        energy is sold under long-term contract to the  
3        Long Island Power Authority.

4 Q.    Please briefly describe National Grid's New York  
5        transmission assets.

6 A.    According to National Grid's witness Schiavone,  
7        "National Grid owns approximately 5,700 miles of  
8        transmission in upstate New York rated at 115kV  
9        and higher, including interconnections with  
10       adjacent control areas." (Schiavone testimony,  
11       p. 5) Mr. Schiavone notes that these assets  
12       include interconnections to New England,  
13       Ontario, and Pennsylvania, as well as part of  
14       the Moses South interface (which carries power  
15       from Quebec). Within New York, National Grid  
16       lines form part of the Central East and Total  
17       East interfaces (between western New York and  
18       the Hudson Valley). National Grid also owns and  
19       operates the Leeds-Pleasant Valley and Athens  
20       Pleasant Valley lines, which carry power down  
21       the Hudson Valley. (Schiavone testimony pp. 5-7)  
22       The Leeds- and Athens-Pleasant Valley lines are

1 part of the UPNY-SENY (Upstate New York -  
2 Southeast New York) interface. (Schiavone  
3 Exh\_\_\_(MLS-1))

4 Q. Can you briefly describe the impact of National  
5 Grid's lines on KeySpan's generation?

6 A. National Grid's lines are a critical part of New  
7 York's bulk transmission system, which allows  
8 upstate generators and imports to compete with  
9 downstate generators, including KeySpan's. Low-  
10 cost imports from upstate and out-of-state  
11 competitors tend to displace sales by KeySpan's  
12 generators, as well as reducing the prices  
13 received by KeySpan's Ravenswood generators.

14 Q. Why do downstate generators tend to lose sales  
15 to upstate and out-of-state competitors?

16 A. Most of the downstate generators are gas-fired  
17 or oil-fired and thus have relatively high fuel  
18 costs. In addition, many of the downstate  
19 generators are relatively old and inefficient.  
20 Because of the generally high operating cost of  
21 downstate generation, there is almost always  
22 some lower-cost generation available from

1 imports or upstate generators, which tend to  
2 displace generation from the more expensive  
3 downstate plants. This results in typical power  
4 flows of thousands of megawatts from western New  
5 York to eastern New York and down the Hudson  
6 Valley to displace a portion of the generation  
7 in New York City and Long Island. Exh.\_\_\_\_

8 (CONSTRAINTS-1, Excerpt from NYISO:  
9 Comprehensive Reliability Planning Process  
10 Supporting Document and Appendices for the Draft  
11 Reliability Needs Assessment, Dec. 21, 2005, pp.  
12 14-17.)

- 13 Q. Please briefly describe the vertical market  
14 power concerns raised by the proposed merger.
- 15 A. As discussed more fully by the Merger Panel, for  
16 almost half the time, KeySpan's NYC generators  
17 are in the same market as upstate New York,  
18 including National Grid's transmission service  
19 territory. The merged company would have a  
20 statewide disincentive to build or upgrade  
21 transmission facilities or facilitate the entry  
22 of competing generators, in order to restrict

1 imports and competition and thereby increase  
2 prices and revenues for its generators.  
3 Moreover, even when NYC is in a separate market,  
4 constraints on National Grid's system can limit  
5 transfers to downstate New York, which can  
6 increase the market prices and revenues received  
7 by KeySpan's generators. Thus the merged  
8 company would have a disincentive to invest in  
9 transmission facilities that would increase  
10 transfers to downstate New York; and the merged  
11 company would also have a perverse incentive to  
12 take or extend outages on the bulk transmission  
13 system, whenever such outages would limit  
14 transfers to downstate New York. Moreover, the  
15 merged company would have a perverse incentive  
16 to reduce maintenance and thereby incur more  
17 frequent unplanned (forced) outages, because the  
18 outages could reduced transfers to downstate New  
19 York.

20 Q. Can you give any indication as to the magnitude  
21 of the perverse incentive?

- 1 A. It is difficult to forecast transmission  
2 constraints and their price impacts, because  
3 they vary with load growth, fuel prices, the  
4 location of new generation and transmission, and  
5 other factors. The recent addition of 1,000 MW  
6 of generating capacity in NYC, and the pending  
7 addition of 660 MW of transmission capacity onto  
8 LI, may reduce downstate price impacts in the  
9 near term. However, load growth and pending  
10 generator retirements downstate and in the lower  
11 Hudson Valley could increase price impacts in  
12 the future. To provide an order of magnitude,  
13 we can consider the impact of a \$1/MWh increase  
14 in NYC prices on Ravenswood's net revenues. In  
15 2005, the Ravenswood units generated about 6.4  
16 million MWh; thus a \$1/MWh increase in the  
17 average NYC price, all else equal, could have  
18 increased Ravenswood's net revenues by over \$6  
19 million.
- 20 Q. How large would a reduction in transfers to NYC  
21 have to be to increase NYC prices by \$1/MWh?

1 A. A reduction in transfers to NYC has the effect  
2 of increasing the amount of NYC load that must  
3 be served by higher-cost NYC generation. The  
4 relationship between NYC generation and price is  
5 given by the NYC Supply Curve. An estimate of  
6 the NYC Supply Curve for June 17, 2004 was  
7 developed by the NYISO for purposes of  
8 benchmarking new software. (NYISO: Market Trials  
9 VI: DAM Benchmarking, presented at Market  
10 Structures Working group, October 4, 2004) The  
11 NYC forecast loads that day ranged from 5,788 MW  
12 to 9,338 MW, well below NYC maximum peak loads  
13 of over 11,000 MW. The supply curve indicates  
14 that as load increased, NYC generation levels  
15 increased from about 2,000 MW to about 5,400 MW,  
16 and NYC prices increased from about \$60/MWh to  
17 about \$120/MWh. This indicates an average price  
18 impact of about \$1.76/MWh per 100 MW increase in  
19 NYC generation. This implies that a 100 MW  
20 reduction in transfers would increase NYC prices  
21 by about \$1.76/MWh on average. Based on this  
22 value, all else equal, an average reduction in

1 transfers of about 60 MW would increase NYC  
2 prices by about \$1/MWh (100 MW divided by \$1.76  
3 times \$1 equals 57 MW).

4 Q. What can you conclude regarding the incentives  
5 for National Grid to exercise vertical market  
6 power in the event of the merger?

7 A. National Grid controls critical transmission  
8 bottlenecks to southeast New York, including the  
9 Hudson Valley, NYC and LI. Reductions in  
10 transfer capability due to planned or unplanned  
11 outages, or failure to invest in new  
12 transmission to increase transfer capability,  
13 could significantly increase prices in southeast  
14 New York, to the financial benefit of any  
15 market-based generation in southeast New York.  
16 An average reduction of 100 MW has the potential  
17 to increase Ravenswood's prices by about  
18 \$1.76/MWh, which could increase Ravenswood's net  
19 revenues by over \$10 million per year (6.4  
20 million MWh times \$1.76/MWh equals \$11.3  
21 million). The impact on NYC customers would be

1 even larger, since the higher prices would also  
2 benefit other NYC market-based generation.

3

4 Impact of National Grid Transmission Constraints on  
5 NYC and LI Prices

6 Q. Does Mr. Schiavone address the impact of  
7 National Grid's lines on prices in New York  
8 City?

9 A. Yes. Mr. Schiavone notes that National Grid's  
10 lines end at Pleasant Valley, in the Hudson  
11 Valley (NYISO Pricing Zone G), where they  
12 interconnect with Consolidated Edison (ConEd)  
13 lines that carry power from upstate New York  
14 into NYC. He observes that the Con Ed lines  
15 pass through two additional zones and  
16 transmission interfaces before reaching NYC.  
17 (Schiavone testimony, p. 7) Finally, he adds  
18 that other lines, not owned by National Grid,  
19 also reach the Hudson Valley (Zone G) from PJM  
20 East, Connecticut, and Zone H (Millwood, in  
21 Westchester County). (Schiavone testimony, p.8)  
22 He concludes that, "As a result, it seems

1 reasonable to assume that any indirect influence  
2 that actions taken by National Grid can have on  
3 generation prices in New York City will be quite  
4 limited." (Schiavone testimony, p.8)

5 Q. What does Mr. Schiavone say about the impact of  
6 National Grid's lines on prices in LI?

7 A. Mr. Schiavone argues that National Grid's lines  
8 do not have a major impact on LI prices. He  
9 states: "Long Island is remote both  
10 geographically and electrically from National  
11 Grid lines and facilities. Long Island is  
12 dependent on ConEd and New England for its  
13 imported power, but, except for some possible  
14 stray loop flows, this power does not flow  
15 through National Grid lines." (Schiavone  
16 testimony, p. 9)

17 Q. Do you agree with Mr. Schiavone's conclusion  
18 that National Grid's lines do not have a major  
19 impact on prices in NYC and LI?

20 A. No, we do not. Wholesale energy (generation)  
21 prices in NYC and LI are determined in spot  
22 markets operated by the NYISO; the market-

1 clearing prices reflect the marginal cost of  
2 supplying an additional MW of NYC or LI load.  
3 As noted above, most generation in NYC and LI is  
4 gas-fired or oil-fired plants with relatively  
5 high fuel costs. Absent access to upstate and  
6 out-of-state resources, the NYISO would have to  
7 rely exclusively on very high-cost downstate  
8 resources, leading to very high wholesale energy  
9 prices. However, National Grid lines provide  
10 access to upstate and out-of-state  
11 hydroelectric, nuclear, and coal-fired plants  
12 with relatively low fuel costs. This permits  
13 the NYISO to transfer thousands of Megawatts of  
14 power from western New York to the Hudson Valley  
15 on National Grid's lines, displacing much of the  
16 higher-cost downstate resources. The result is  
17 lower wholesale energy prices in NYC and LI.

18 Q. Mr. Schiavone observes that power can reach Zone  
19 G (Hudson Valley) through lines not owned by  
20 National Grid, including lines from PJM East,  
21 Connecticut, and Zone H (Westchester County).

1           Are these other lines adequate substitutes for  
2           National Grid's lines?

3    A.   No.   Zone H is downstream from Zone G, so it is  
4           generally on the high-cost side of upstate  
5           constraints.  Lines to PJM East (New Jersey) and  
6           Connecticut connect to regions that, like  
7           downstate New York, are largely dependent on  
8           relatively high-cost gas- and oil-fired  
9           generation; moreover, the lines have limited  
10          capacity.  Thus the other interconnections to  
11          Zone G could not fully compensate for  
12          constraints that reduced transfers on National  
13          Grid's lines.  Finally, PJM East and Connecticut  
14          are not part of the NYISO and coordination  
15          between them and the NYISO is imperfect, which  
16          can limit otherwise-efficient imports,  
17          especially on short notice.

18   Q.   Is there a more competitive location in New York  
19          than the Hudson Valley (Zone G)?

20   A.   Yes.  The Marcy Substation, near Utica, is  
21          generally a more competitive location in New  
22          York, because it is the junction of major lines

1 from the north and west, accessing  
2 hydroelectric, nuclear, and coal-fired power  
3 from upstate New York, Pennsylvania, Ontario and  
4 Quebec, as well as major lines delivering power  
5 to the east (Albany) and southeast (Hudson  
6 Valley). Unlike the Hudson Valley, Marcy is  
7 west of the Central East and Total East  
8 constraints. Because of its central location,  
9 the NYISO uses the price at Marcy as its  
10 "Reference Price" for wholesale energy in New  
11 York.

12 Q. Please summarize the impact of National Grid's  
13 transmission system on downstate prices.

14 A. Downstate prices are almost always higher than  
15 the reference price at Marcy, due to line losses  
16 and transmission constraints encountered by the  
17 power transfers from Marcy to downstate loads.  
18 The price at each location is the sum of the  
19 reference price (marginal cost of energy),  
20 marginal line losses, and marginal congestion  
21 costs, reflecting the impact of transmission  
22 constraints. (The NYISO actually posts

1 congestion costs to Marcy, rather than from  
2 Marcy, so the posted marginal congestion costs  
3 in downstate New York are generally negative and  
4 must be subtracted from the reference price to  
5 calculate the higher downstate price.)

6 Q. Can you briefly explain marginal line losses?

7 A. Power lines offer some resistance to the flow of  
8 power; this heats up the lines, dissipating some  
9 of the power. The NYISO accounts for this by  
10 adding marginal line losses to the price,  
11 reflecting the cost of the additional line  
12 losses incurred by an additional MW of load at  
13 that location.

14 Q. Can you briefly explain marginal congestion  
15 costs?

16 A. Marginal congestion costs refer to the cost  
17 incurred to satisfy transmission constraints.  
18 As long as power flows are below the limits set  
19 by transmission constraints, the NYISO can serve  
20 downstate load using the low-cost upstate  
21 generation or imports, and marginal congestion  
22 costs are zero. However, higher loads tend to

1           require larger power flows. If the flow on a  
2           line reaches its limit, the constraint is said  
3           to "bind," and additional load on the downstream  
4           side of the constraint must be served by a  
5           higher-cost generator on the downstream side in  
6           order to avoid overloading the transmission  
7           line. The need to suddenly switch from low-cost  
8           transfers to higher-cost downstate generation  
9           can result in a sudden, large jump in prices on  
10          the downstream side of the binding constraint.

11 Q.    Please explain how constraints affect the size  
12          of the market.

13 A.    A binding constraint causes the market to split  
14          in two, because prices downstream from the  
15          constraint reflect the higher marginal cost of  
16          downstate generation. Thus if the Central East  
17          interface binds, prices in Albany and points  
18          south will jump because additional load on the  
19          east side of the constraint must be served by  
20          additional higher-cost generation on the east  
21          side. In that case, Albany will be part of the  
22          eastern market. On the other hand, if the

1 binding constraint is the Leeds-Pleasant Valley  
2 line south of Albany, then prices in Albany will  
3 remain low (because Albany is on the upstream  
4 side of that constraint), and the jump in prices  
5 will be limited to the Hudson Valley and points  
6 south. In that case, Albany will be part of the  
7 western market.

8 Q. If a binding constraint is downstream from  
9 National Grid's territory, can National Grid's  
10 transmission still impact downstate prices?

11 A. Yes. For example, congestion may increase on  
12 National Grid's system to the point where it  
13 limits transfers below the level at which the  
14 downstate lines were constrained. In that case,  
15 the binding constraint would move from the  
16 downstate line to the upstate line. The  
17 additional reduction in transfers would likely  
18 cause a further increase in downstate prices.

19 Q. Is congestion susceptible to the exercise of  
20 vertical market power?

21 A. Yes. Congestion varies with load, generator and  
22 transmission outages, transmission investments

1 and other factors. These features raise the  
2 possibility that congestion could be subject to  
3 manipulation, for example by altering  
4 transmission investments or maintenance, in  
5 order to exert vertical market power. This was  
6 the second example raised by the Commission's  
7 VMP Statement, and is further discussed by  
8 Staff's Merger Panel.

9 Q. Can you give a real-world example of congestion  
10 on National Grid lines impacting downstate  
11 prices?

12 A. Yes, we have provided an example as Exhibit \_\_\_\_  
13 (CONSTRAINTS-2). The NYISO posts congestion by  
14 location for both its day-ahead and real-time  
15 markets. We selected June 1, 2006 because on  
16 that day, the NYISO recorded moderate congestion  
17 on National Grid's Leeds-Pleasant Valley line in  
18 the day-ahead market (run on the morning of May  
19 31) and severe congestion on the same line in  
20 the real-time market, due to a ThunderStorm  
21 Alert (TSA).

1 Q. Please briefly explain NYISO's day-ahead and  
2 real-time markets.

3 A. In the day-ahead market, held the morning of the  
4 prior day, NYISO schedules generation to serve  
5 load at least cost, subject to transmission  
6 constraints, based on bids submitted by 5 AM.  
7 In the real-time market, the NYISO adjusts the  
8 generation to deal with actual (metered) load if  
9 different from day-ahead bid load, and to deal  
10 with generator or transmission outages that had  
11 not been forecast day-ahead. The NYISO  
12 calculates day-ahead prices at hourly intervals  
13 and real-time prices at 5-minute intervals,  
14 based on those same day-ahead and real-time  
15 bids. The prices reflect the market-clearing  
16 price, i.e. the marginal cost of serving an  
17 additional MW of load. These prices vary by  
18 location, and so are referred to as location-  
19 based marginal-cost prices (LBMPs).

20 Q. What is a ThunderStorm Alert?

21 A. A ThunderStorm Alert (TSA) is a reliability rule  
22 called by the NYISO when severe thunderstorms

1           threaten power lines in the Hudson Valley.  
2           Normally, the NYISO operates the transmission  
3           system with enough spare capacity on the lines  
4           to protect against the contingency of the loss  
5           of one major facility; this is referred to as  
6           "single contingency" operation.  However, during  
7           a TSA, the NYISO operates the transmission  
8           system more conservatively, to protect against  
9           the potential loss of two major facilities at  
10          once from lightning strikes; this is referred to  
11          as "double contingency" operation.  Among the  
12          facilities at risk are National Grid's lines  
13          from Leeds and Athens to Pleasant Valley.  The  
14          effect of a TSA is to operate the system as if  
15          one facility, such as the Athens-Pleasant Valley  
16          line, were already out of service.  Thus a TSA  
17          can illustrate the potential impact on prices of  
18          an unexpected outage of National Grid's Athens-  
19          Pleasant Valley line.

20    Q.    Please briefly describe the day-ahead prices for  
21          June 1, 2006.

1 A. The chart of day-ahead prices shows that prices  
2 increased as load increased, reflecting the need  
3 to run higher-cost generators. Prices also  
4 increased in the same direction as power flowed,  
5 from west (Mohawk Valley) to east (Capital) and  
6 down the Hudson Valley to NYC and LI. Notably,  
7 from hours 12 to 16 (noon to 5 PM), prices in  
8 the Hudson Valley and Ravenswood in NYC jumped  
9 well above prices in the Capital zone. This  
10 jump was due to congestion on National Grid's  
11 Leeds-Pleasant Valley line during those hours of  
12 peak load, as shown by the list of day-ahead  
13 constraints. Congestion increased the price at  
14 Ravenswood by an average of \$7.66 per MWh  
15 between noon and 5 PM.

16 Q. Please briefly describe the real-time market for  
17 June 1, 2006.

18 A. During the morning hours, real-time prices  
19 generally followed the day-ahead prices. Real-  
20 time (actual) loads were above the day-ahead  
21 forecast; NYC loads peaked at 9,020 MW, well  
22 above the day-ahead forecast peak of 7,931 but

1 well below the summer peak of over 11,000 MW.  
2 Around 11 AM, real-time prices began to rise  
3 moderately, to \$136/MWh during hour 12 (from  
4 noon to 1 PM); at that time there was no  
5 congestion to NYC or LI. However, at 1 PM,  
6 significant congestion appeared on the Leeds-  
7 Pleasant Valley line, and at about 1:15 PM a TSA  
8 was called, requiring a reduced flow on Leeds-  
9 Pleasant Valley (in case of an outage on the  
10 Athens-Pleasant Valley line), as shown by the  
11 list of real-time constraints for that day. To  
12 reduce the flow on National Grid's lines,  
13 downstate generation had to be suddenly  
14 increased, while upstate generation was reduced.  
15 The chart "Total East Real-Time Flows" shows the  
16 resulting reduction of about 1,000 MW in real-  
17 time transfers to southeastern New York over the  
18 Total East interface. Exh.\_\_\_\_ (CONSTRAINTS-2)  
19 To accomplish this, the NYISO had to call on  
20 expensive downstate generators, leading to a  
21 spike in prices south of Pleasant Valley, with  
22 average real-time prices exceeding \$500 per MWh

1 for nine hours (1 PM to 10 PM). The congestion  
2 component of Ravenswood's real-time prices  
3 averaged over \$400 per MWh during this period.

4 Q. What does this example show about the potential  
5 downstate price impacts of constraints on  
6 National Grid's lines?

7 A. This example illustrates the fact that National  
8 Grid's lines can, in fact, have a major impact  
9 on prices in NYC and LI. In the day-ahead  
10 market, constraints on National Grid's lines  
11 increased prices at Ravenswood in NYC over a 5-  
12 hour period by an average of over \$7 per MWh.  
13 In the real-time market, a reduction in transfer  
14 capability due to a TSA, equivalent to the  
15 impact of an unexpected outage on National  
16 Grid's Athens-Pleasant Valley line, caused  
17 severe price increases from the Hudson Valley  
18 south to NYC and LI. Real-time prices at  
19 Ravenswood increased by over \$300 per MWh, from  
20 \$136 before the TSA to an average of \$444 during  
21 the TSA (averaged between 1 PM and 10 PM).

1 Q. Does congestion in New York occur only during  
2 summer peak periods?

3 A. No. While congestion tends to be higher in the  
4 summer months, congestion in New York is a daily  
5 occurrence, as shown in a graph of bid  
6 production cost impacts for 2005 (bid production  
7 cost impacts are calculated as the change in  
8 generation costs due to congestion). (NYISO:  
9 Congestion Impact Update, Electric System  
10 Planning Working Group, March 14, 2006)

11 Q. How large an impact can National Grid's lines  
12 have on transfers into NYC?

13 A. The Central-East interface has a nominal  
14 transfer capability of 2,850 MW, while the UPNY-  
15 SENY interface has a nominal transfer capability  
16 of 5,100 MW. Exh.\_\_\_\_ (CONSTRAINTS-1, Table 4.2)  
17 National Grid's Leeds-Pleasant Valley line has a  
18 transfer capability of 1724 MW (emergency  
19 thermal rating), limited by a potential outage  
20 on its Athens-Pleasant Valley line. (NYISO:  
21 Comprehensive Reliability Planning Process  
22 Supporting Document and Appendices for the Draft

1           Reliability Needs Assessment, Dec. 21, 2005, p.  
2           51, Table 11.1.3) According to the NYISO, an  
3           outage on National Grid's Leeds-Pleasant Valley  
4           line can decrease transfer capabilities across  
5           Total East (which includes the Central East  
6           constraint) by 925 MW during summer months and  
7           300-400 MW during winter months. ("New York ISO  
8           Transmission facility Maintenance Outage Impact  
9           Report," NYISO Outage Scheduling Manual, May 30,  
10          2002, Appendix B)

11    Q.    Can you estimate the potential impact on NYC  
12          prices of an outage on Leeds-Pleasant Valley?

13    A.    The potential impacts depend critically on load  
14          levels, existing transfers, and the extent to  
15          which the outage is forecasted, among other  
16          factors. Assuming a forecasted outage reduced  
17          transfers by 925 MW, the price impact in the  
18          day-ahead market could be about \$16/MWh (925 MW  
19          times \$1.76/MWh per 100 MW equals \$16.3  
20          million). Assuming Ravenswood was generating at  
21          its average 2005 capacity factor of 30%, its net  
22          revenues would increase by about \$280,000 per

1 day (30% times 2,400 MW times \$16/MWh times 24  
2 hours/day equals \$276,000/day). If the outage  
3 was not forecasted, price impacts in the real-  
4 time market would likely be higher, because the  
5 NYISO would have to rely on even more expensive  
6 quick-start resources to replace the lost  
7 transfers. The TSA on June 1, 2006, equivalent  
8 to an unexpected outage, increased real-time  
9 prices in NYC and LI by an average of over \$300  
10 per MWh for 9 hours.

11 Q. What are the current levels of congestion costs  
12 in the NYISO's day-ahead markets due to  
13 constraints on National Grid's lines?

14 A. For congestion in the day-ahead markets, the  
15 NYISO has reported the costs of "unhedged"  
16 congestion; this multiplies the marginal cost of  
17 congestion by the amount of load that must be  
18 served by the more-expensive downstate  
19 generation (i.e. it credits load with the  
20 congestion rents it receives from the transfers  
21 that do occur). In 2005, unhedged congestion on  
22 the Central-East interface cost about \$80

1 million (9.2% plus 2.5% of the 2005 total \$685  
2 million), while unhedged congestion on Leeds-  
3 Pleasant Valley cost about \$119 million (17.3%  
4 of the 2005 total \$685 million). (NYISO:  
5 Congestion Impact Update, Electric System  
6 Planning Working Group, March 14, 2006)

7 Q. What are the current levels of congestion costs  
8 in the NYISO's real-time markets due to  
9 constraints on National Grid's lines?

10 A. The NYISO's Independent Market Advisor reported  
11 that real-time congestion on Leeds-Pleasant  
12 Valley due to TSAs "... accounted for  
13 approximately \$60 million of the [real-time]  
14 congestion costs incurred in the Capital to  
15 Hudson Valley corridor." (Potomac Economics,  
16 Ltd., Independent Market Advisor to the New York  
17 ISO, 2005 State of the Market Report: New York  
18 ISO, August 2006, p. 64) The costs of real-time  
19 congestion such as caused by unexpected outages  
20 or TSAs are in addition to the costs of day-  
21 ahead congestion. They represent the cost of  
22 expensive downstate generation that must be

1 purchased in the real-time market to replace  
2 cheaper upstate generation. Real-time  
3 congestion costs are borne by loads, either as  
4 the congestion component of real-time prices or  
5 through an extra charge (uplift) added to  
6 wholesale prices.

7

8 NYISO Oversight of Transmission Maintenance

9 Q. Could transmission maintenance on National Grid  
10 lines raise downstate generation prices?

11 A. Yes, as admitted by National Grid witness  
12 Schiavone:

13

14 "There are only a limited number of ways,  
15 even in theory, in which a transmission  
16 owner ("TO") like National Grid could  
17 withdraw or limit capacity on its upstate  
18 transmission system in order to limit power  
19 flows into New York City (Zone J) and thus  
20 potentially raise generation prices.  
21 Hypothetical strategies for withdrawing  
22 capacity on National Grid's upstate lines  
23 include taking outages or extending  
24 outages..." (Schiavone testimony, p. 3)

25

26 Q. How does National Grid propose to mitigate such  
27 market power?

28 A. National Grid witness Schiavone argues that such  
29 exercise of vertical market power is precluded

1 by NYISO oversight and control of the New York  
2 transmission system, NYISO market monitoring and  
3 investigative authority, NYISO penalties for  
4 extending scheduled outages under Attachment N  
5 to the NYISO Market Services Tariff, FERC-  
6 enforced Standards of Conduct, training of  
7 transmission staff, and market participants'  
8 ongoing scrutiny of transmission operations.  
9 (Schiavone testimony, pp. 3-4).

10 Q. According to Mr. Schiavone, what oversight and  
11 control does the NYISO exercise over scheduled  
12 outages?

13 A. Mr. Schiavone quotes the NYISO Agreement, sec.  
14 6.04:

15 The ISO shall have the authority to approve  
16 or deny all requests for transmission  
17 outages on Transmission Facilities Under  
18 ISO Operational Control [A-1 facilities] ....  
19 The ISO shall be notified of the  
20 maintenance scheduled on Transmission  
21 Facilities Requiring ISO Notification [A-2  
22 facilities], and shall advise the  
23 Transmission Owner of potential adverse  
24 reliability impacts in accordance with the  
25 ISO OATT.  
26

1 Q. Does the NYISO oversight and control over  
2 scheduled outages preclude National Grid's  
3 scheduling an outage to raise downstate prices?

4 A. No, it does not. The physical operation and  
5 maintenance of the transmission system is  
6 performed by National Grid and other  
7 transmission owners. While the NYISO has  
8 authority to deny their requests for an outage,  
9 this authority is limited to reliability  
10 impacts, not price impacts. Mr. Schiavone  
11 admitted this in response to DPS-239, #1.

12 Q. How does Niagara Mohawk request an outage of a  
13 major transmission line?

14 A. The New York ISO, through market participation,  
15 has developed a manual, "The NYISO Outage  
16 Schedule Manual," which was approved by the  
17 Operating Committee on October 28, 2004. This  
18 manual contains the rules by which Transmission  
19 Operators and Generators schedule outages of  
20 equipment. In the case of a Transmission  
21 Operator requesting a facility outage, the  
22 manual specifically states that the NYISO "...

1 coordinates all requests for transmission  
2 outages based on their potential impact on  
3 system reliability". The manual does not  
4 provide for the NYISO to perform any analysis of  
5 the impact of the outage on the markets.

6 Q. What is meant by "system reliability"?

7 A. The NYISO employs specific reliability criteria  
8 consistent with Reliability Rules established by  
9 the New York State Reliability Council. These  
10 rules include locational capacity requirements  
11 that ensure sufficient generating capacity in  
12 NYC to supply 80% of NYC peak loads, and on LI  
13 to supply 99% of LI peak loads. Because the  
14 reliability rules require additional generation  
15 downstate to serve load reliably on even the  
16 hottest days, the NYISO is generally able to  
17 respond to transmission outages (or, in the case  
18 of TSAs, by the threat of transmission outages)  
19 by further increases in downstate generation,  
20 just at higher cost.

21 Q. Does the enforcement of reliability criteria  
22 prevent price increases?

1 A. No. In general, enforcement of reliability  
2 criteria is likely to increase costs and  
3 (downstate) prices. For example, in order to  
4 prevent an overload on the Leeds-Pleasant Valley  
5 line (which would violate one of the reliability  
6 criteria), the NYISO will shift generation from  
7 lower-cost upstate resources to higher-cost  
8 downstate resources. This will tend to increase  
9 downstate prices, in the interests of ensuring  
10 reliability.

11 Q. Does the Outage Scheduling Manual provide  
12 direction to the NYISO regarding approval of  
13 outage requests by transmission owners?

14 A. Yes. The Outage Manual states:

15 ... the NYISO will defer, postpone, or cancel  
16 requested transmission outages of  
17 facilities under NYISO operational control  
18 if a contingency on a NYISO monitored  
19 facility will result in a reliability  
20 criteria violation. Also, the NYISO will  
21 defer the requested outage if notification  
22 is not received with the minimum  
23 notification time requirements. Otherwise,  
24 the NYISO will approve the requested  
25 outage, or reschedule the outage as agreed  
26 to by the requesting TO. (Outage Scheduling  
27 Manual, Sec. 1.2.3, Facility Outage  
28 Scheduling Procedures, pp. 1-3 to 1-4,  
29 emphasis added)

- 1  
2 Q. Turning to market monitoring and investigative  
3 authority, has the NYISO ever audited a  
4 transmission system outage taken by Niagara  
5 Mohawk to verify the need for the facilities to  
6 be out of service?
- 7 A. No, in interrogatory DPS - 253, Michael  
8 Schiavone responded directly to the  
9 interrogatory that the NYISO has never audited  
10 an outage taken by Niagara Mohawk.
- 11 Q. What does this mean to the market?
- 12 A. It means the NYISO has not performed an analysis  
13 of Niagara Mohawk's need to schedule a  
14 transmission outage or its impact on the market.  
15 As a result, it is possible that Niagara Mohawk  
16 could take an outage without anyone from the  
17 NYISO auditing the need for the outage or  
18 measuring the impact on the market.
- 19 Q. If an outage is taken, is there any requirement  
20 that the outage be completed as quickly as  
21 possible?

1 A. No. In some cases, transmission owners have  
2 worked around to clock to complete outages as  
3 quickly as possible, but as that will often  
4 increase the maintenance costs, it is not  
5 standard procedure. Ownership of a downstate  
6 generator would add a significant disincentive  
7 to complete an outage as quickly as possible.

8 Q. Mr. Schiavone states that the NYISO provides  
9 penalties for extending scheduled outages under  
10 Attachment N to the NYISO Market Services  
11 Tariff. Would this adequately mitigate vertical  
12 market power?

13 A. No. Attachment N refers to the allocation among  
14 transmission owners of congestion costs and  
15 revenues, which are components of their  
16 respective Transmission Service Charges (TSCs),  
17 a FERC-approved formula rate. The allocation  
18 formulas were changed in 2004 to ensure that  
19 congestion costs, due to an outage by one  
20 transmission owner, are allocated to that  
21 transmission owner rather than spread across all  
22 transmission owners. While assignment of outage

1 costs to the responsible transmission owner is  
2 desirable, these are not "penalties," but merely  
3 part of the calculation of net congestion  
4 revenues. Any costs (not "penalties") allocated  
5 to National Grid under Attachment N are  
6 ultimately flowed through to customers, via an  
7 increase in their TSC payments. Because the  
8 merged company's transmission function would  
9 still be subject to cost-of-service regulation,  
10 assignment to shareholders of penalties  
11 associated with National Grid's provision of  
12 transmission service is ultimately a question of  
13 prudence.

14 Q. Could the maintenance incentives be strengthened  
15 simply by setting firm rates, including fixed  
16 levels of TSCs?

17 A. Firm targets for TSC charges would be  
18 problematic. First, TSCs are based on embedded  
19 costs net of congestion revenues, and  
20 transmission owners are subject to cost-of-  
21 service regulation. Refusing recovery of higher  
22 TSCs could require a finding of imprudence.

1           Second, a firm target for TSCs could actually  
2           lead to perverse maintenance incentives.  
3           Transmission owners receive congestion revenues  
4           based on the amount of MWs that flow across  
5           congested interfaces and the congestion prices  
6           across the interfaces (i.e. the difference in  
7           congestion price across each interface). If a  
8           transmission owner reduced maintenance and  
9           consequently incurred greater outages, its MW  
10          flows might decline but its congestion prices  
11          would likely increase. If congestion prices  
12          increase by a larger percentage than the  
13          decrease in flows, the transmission owner's  
14          congestion revenues would actually increase.  
15          Thus firm transmission rates, including fixed  
16          levels of TSCs, could actually permit a  
17          transmission owner to profit from increased  
18          congestion.

19    Q.    Do you have any comments regarding FERC-enforced  
20          Standards of Conduct, training of transmission  
21          staff, or market participants' ongoing scrutiny  
22          of transmission operations?

1 A. These measures do not adequately mitigate  
2 concerns over vertical market power. They only  
3 indicate that the exercise of vertical market  
4 power, or the suspicion of same, may create  
5 significant controversy in future rate cases and  
6 prudence proceedings. As the NYPSC said in its  
7 Vertical Market Power Statement: "Recognizing  
8 that vigilant regulatory oversight cannot timely  
9 identify and remedy all abuses, it is preferable  
10 to properly align incentives in the first  
11 instance." (VMP Statement, Appendix I, p. 1)

12

13 Impact on NYISO Governance

14 Q. Could the NYISO change its rules and procedures  
15 to directly control transmission maintenance and  
16 investment?

17 A. No, the NYISO does not have the resources to  
18 take over those tasks. The transmission owners  
19 physically build, maintain and operate the  
20 transmission system; the NYISO relies on the  
21 cooperation of the transmission owners to carry  
22 out those tasks efficiently. Recognizing this,

1 the NYISO has attempted to provide financial  
2 incentives to transmission owners, such as the  
3 maintenance incentives incorporated into  
4 Attachment N. However, the financial incentives  
5 of Attachment N operate in the context of  
6 transmission owners subject to rate-of-return  
7 regulation, not market-based generation.

8 Q. Can National Grid influence the development of  
9 NYISO rules and procedures regarding  
10 transmission maintenance and investment?

11 A. Yes. Ms. Saidi has testified that:

12 National Grid has strongly supported the  
13 following policy initiatives and proposals  
14 in the stakeholder processes for the NYISO  
15 and the New York State Reliability Council  
16 ("NYSRC"), and in numerous regulatory  
17 proceedings before the FERC. Each of these  
18 policy initiatives and proposals recognize  
19 transmission as the critical link to  
20 delivering to customers the benefits of  
21 electric industry restructuring and are  
22 designed to result in improved generation  
23 competition and reductions in the overall  
24 cost of delivered power. (Saidi testimony,  
25 p. 9)

26  
27 Q. Have National Grid's policy initiatives been  
28 influenced by its own financial incentives?

1 A. Yes. For example, the impetus for maintenance  
2 incentives, ultimately filed as Attachment N,  
3 was by National Grid, which was concerned that  
4 upstate customers were paying part of the cost  
5 of downstate congestion. This illustrates the  
6 importance of financial incentives in the  
7 development of the NYISO market rules and  
8 procedures.

9 Q. How would the proposed merger impact National  
10 Grid's financial incentives?

11 A. Under the proposed merger, National Grid would  
12 gain an ownership interest in New York State  
13 generators, including market-based generators,  
14 which would radically change its financial  
15 incentives. The merged company would have the  
16 ability and incentives to exercise vertical  
17 market power, in order to increase its market-  
18 based revenues from downstate generation.  
19 Moreover, National Grid's focus on transmission  
20 would inevitably be diluted, if not reversed.  
21 We could no longer count on National Grid  
22 assigning its best employees and resources to

1 the management of transmission projects or the  
2 development of transmission proposals at the  
3 NYISO.

4 Q. Please briefly describe the NYISO's governance  
5 process by which its rules and procedures can be  
6 changed.

7 A. The NYISO is a non-profit corporation employing  
8 shared governance with its stakeholders. Under  
9 shared governance, the development of rules and  
10 procedures is carried out in all-parties  
11 meetings, and proposals are subject to votes by  
12 stakeholders at the NYISO's Business Issues,  
13 Operating, and Management Committees. Shared  
14 governance was adopted due to the complexity of  
15 New York's electric system and the need to  
16 carefully coordinate the activities of  
17 generators and other suppliers, transmission  
18 owners, public power, and end use customers.  
19 Each sector is allocated a certain percentage of  
20 the votes, designed to balance the competing  
21 financial interests of the stakeholders. NYISO  
22 rules and procedures must be filed as tariffs

1 and approved by the Federal Energy Regulatory  
2 Commission (FERC). The NYISO can propose tariff  
3 changes under FERC Section 205 only with  
4 approval of 58% of the votes of the Management  
5 Committee. Absent such approval, the NYISO can  
6 file proposed tariff changes under Section 206,  
7 but faces a much higher burden of proof.

8 Q. Please briefly explain sector voting at the  
9 NYISO.

10 A. Under the NYISO sector voting, each of the four  
11 transmission owners has 5% of the total vote  
12 (for a total of 20%), while generators and other  
13 suppliers have a total of 43% of the total vote.  
14 Public power and end-use sectors have the  
15 remaining 37% of the total vote. Approval by  
16 the Management Committee requires 58% support,  
17 so a proposal can be blocked by opposition of  
18 over 42% of the total vote. Note that the  
19 combined votes of all generators and other  
20 suppliers are barely sufficient to block  
21 approval of a proposal at the Management  
22 Committee. This was designed to protect sellers

1 from tariff changes promoted by buyers solely to  
2 reduce prices. At the same time, it is  
3 difficult for sellers to block proposals  
4 designed to improve the efficiency of the  
5 market, because buyers may be able to negotiate  
6 with one or more sellers to obtain the  
7 additional 1% required to pass a proposal.

8 Q. Are votes at the Management Committee ever  
9 close?

10 A. Yes. Many votes, particularly involving market  
11 power mitigation, have been very close, with  
12 intense negotiations to achieve the 58% minimum.  
13 For example, the NYISO originally had no  
14 explicit cap on energy bids; there was only an  
15 implicit cap of \$9,999.99 per MWh (the largest  
16 value that the software accepted). During the  
17 first months of NYISO's operation, prices  
18 sometimes spiked to those levels not due to true  
19 shortages, but simply due to design flaws in the  
20 NYISO's rules and procedures. Moreover, it  
21 became evident that, at times of true shortages,  
22 there was not adequate demand response to limit

1 prices. This made the NYISO's energy markets  
2 very susceptible to market power abuse. To  
3 mitigate this, the NYPSC worked with market  
4 participants to develop an overall energy bid  
5 cap of \$1,000 per MWh. After lengthy  
6 negotiations, this bid cap was approved by the  
7 Management Committee on June 5, 2000 by a vote  
8 of 63.15%, including unanimous support from  
9 transmission owners, and ultimately was approved  
10 by FERC. If just two of the five transmission  
11 owners at that time had voted no, the motion  
12 would have failed.

13 Q. How would the proposed merger impact NYISO's  
14 governance?

15 A. The merger would drastically alter National  
16 Grid's financial incentives, since shareholders  
17 would be the beneficiaries of 100% of the  
18 profits of the Ravenswood generators. Thus  
19 National Grid's financial interests would become  
20 aligned with sellers, in effect increasing the  
21 sellers' share to 48%. This would significantly  
22 alter the balance of interests at the NYISO

1           Committees and lower-level working groups,  
2           making it much more difficult to develop rules  
3           and procedures to deal with market power and  
4           mitigation. Moreover, if two other transmission  
5           owners were also allowed to own market-based  
6           generation, the voting strength of the sectors  
7           aligned with sellers would increase to 58%,  
8           sufficient to push through tariff changes  
9           favorable to sellers without any consideration  
10          given to buyers.

11 Q.    Does this conclude your testimony at this time?

12 A.    Yes.
